PROBLEM 2.7

$$(a) \int_{-T}^T x_o(t) dt = \int_{-T}^0 x_o(t) dt + \int_0^T x_o(t) dt \quad ; \quad x_o(t) = -x_o(-t)$$

$$\therefore \int_{-T}^0 x_o(t) dt = - \int_{-T}^0 x_o(-t) dt \Big|_{z=-T} = \int_{-T}^0 x_o(\tau) d\tau = - \int_0^T x_o(\tau) d\tau$$

$$\therefore \int_{-T}^T x_o(t) dt = 0$$

(c) $x_o(0) = -x_o(-0) = -x_o(0)$. The only number with $a = -a$ is $a = 0$ so this implies $x_o(0) = 0$.
 $x(0) = x_e(0) + x_o(0) = x_e(0)$.

PROBLEM 2.8

(a) Let $z(t)$ be the sum of two even functions $x_1(t)$ and $x_2(t)$. To show that $z(t)$ is even, we need to show that $z(t) = z(-t)$ for all t . This is easy to show, since $z(t) = x_1(t) + x_2(t)$ and $z(-t) = x_1(-t) + x_2(-t)$ (since to get $z(-t)$ we just plug in $-t$ everywhere for t , which amounts to just plugging in $-t$ in $x_1(t)$ and $x_2(t)$). Now since $x_1(t)$ and $x_2(t)$ are even, by definition $x_1(t) = x_1(-t)$ and $x_2(t) = x_2(-t)$ so $x_1(t) + x_2(t) = x_1(-t) + x_2(-t)$ so $z(t) = z(-t)$.

(b) Let $x_1(t)$ and $x_2(t)$ be two odd functions. Then $x_1(-t) + x_2(-t) = -x_1(t) + (-x_2(t)) = -(x_1(t) + x_2(t))$ which shows that $x_1(t) + x_2(t)$ is odd.

(c) Let $z(t) = x_1(t) + x_2(t)$ as in part a, where now $x_1(-t) = x_1(t)$ and $x_2(-t) = -x_2(t)$. We need to show that $z(t) \neq z(-t)$, $z(t) \neq -z(-t)$. Consider that $z(-t) = x_1(-t) + x_2(-t) = x_1(t) - x_2(t)$. In order to have $z(t)$ be even, we would therefore need to have $x_1(t) + x_2(t) = x_1(t) - x_2(t)$ for all t , which is equivalent to having $x_2(t) = -x_2(t)$ for all t , which is not possible for nonzero $x_2(t)$. Similarly, in order to have $z(t)$ be odd, we would need to have $z(t) = -z(-t) \implies x_1(t) + x_2(t) = x_2(t) - x_1(t)$, which is not possible for nonzero $x_1(t)$. So the sum of an even and odd function must be neither even nor odd.

(d) Let $z(t) = x_1(t)x_2(t)$ where $x_1(t) = x_1(-t)$ and $x_2(t) = x_2(-t)$. Then $z(-t) = x_1(-t)x_2(-t) = x_1(t)x_2(t) = z(t)$ which shows that $z(t)$ is even.

(e) Let $z(t) = x_1(t)x_2(t)$, where $x_1(t) = -x_1(-t)$ and $x_2(t) = -x_2(-t)$. Clearly $z(t)$ is even because $z(-t) = x_1(-t)x_2(-t) = (-x_1(t))(-x_2(t)) = x_1(t)x_2(t) = z(t)$, which is the definition of evenness.

(f) Let $z(t) = x_1(t)x_2(t)$, where $x_1(t) = -x_1(-t)$ and $x_2(t) = x_2(-t)$. Clearly $z(t)$ is odd because $z(-t) = x_1(-t)x_2(-t) = (-x_1(t))x_2(t) = -x_1(t)x_2(t) = -z(t)$, which is the definition of oddness.

P 2.9

$$x_o(t) = \frac{x(t) - x(-t)}{2}$$

$$x_e = \frac{x(t) + x(-t)}{2}$$

$$x(t) = x_o(t) + x_e(t)$$

PROBLEM 2.10

(a) $\sin(t) = \sin(t + n2\pi)$ for any integer n , so $7\sin(3t) = 7\sin(3t + n2\pi) = 7\sin(3(t + n\frac{2\pi}{3}))$; therefore $x(t)$ is periodic with fundamental period $T_0 = \frac{2\pi}{3}$ and fundamental frequency $\omega_0 = \frac{2\pi}{T_0} = 3$.

(b) $\sin(8(t + \frac{2\pi}{8}) + 30) = \sin(8t + 2\pi + 30) = \sin(8t + 30)$.
 $\omega_0 = 8$ and $T_0 = \frac{2\pi}{8} = \frac{\pi}{4}$.

(c) $e^{jt} = \cos(t) + j\sin(t)$ is periodic with fundamental period 2π , so e^{j2t} is periodic with fundamental period $\frac{2\pi}{2} = \pi$, and fundamental frequency $\omega_0 = 2$.

(d) $\cos 2t + \sin 5t$

$$T_0 = \frac{2\pi}{10} = \pi/5 (\text{s}), \text{ periodic}$$

$$(f) e^{j15t} - e^{j20t}$$

e^{j15t} & e^{j20t} are both periodic

$$\frac{20}{15} = \frac{4}{3} \Rightarrow k_0 = 3 \therefore T_0 = 3T_1 = \frac{2\pi}{5} \text{ s}$$

PROBLEM 2.13

(a) For $x_1(t) + x_2(t)$ to be periodic we need some number T such that $x_1(t+T) + x_2(t+T) = x_1(t) + x_2(t)$ for all t . This can only be true if $x_1(t+T) = x_1(t)$ and $x_2(t+T) = x_2(t)$, which can only be true if $T = k_1 T_1$ and $T = k_2 T_2$ (T is an integer multiple of both the periods). So we need there to be some integers k_1 and k_2 such that $k_1 T_1 = k_2 T_2 \implies \frac{T_1}{T_2} = \frac{k_2}{k_1}$.

(b) Put $\frac{k_2}{k_1}$ in its most reduced form $\frac{n}{m}$ by canceling any common terms in the numerator and denominator; then $T_0 = n T_2 = m T_1$.

PROBLEM 2.17

$$\int_{-\infty}^{\infty} \delta(at-b) \sin^2(t-c) dt$$

$$\delta(at-b) = \delta(a(t-b/a)) = \frac{1}{a} \delta(t-b/a)$$

$$\delta(t-b/a) \sin^2(t-c) = \sin^2(b/a-c) \delta(t-b/a)$$

$$\begin{aligned} \therefore \int_{-\infty}^{\infty} \delta(at-b) \sin^2(t-c) dt &= \frac{1}{a} \sin^2(b/a-c) \int_{-\infty}^{\infty} \delta(t-b/a) dt \\ &= \frac{1}{a} \sin^2(b/a-c) \end{aligned}$$

PROBLEM 2.18

$$(a) \quad y(t) = \int_{-\infty}^{\infty} x(\tau) [\delta(\tau+5) - \delta(\tau-5)] d\tau$$

$$x(\tau) \delta(\tau-a) = x(a) \delta(\tau-a)$$

$$\therefore y(t) = x(-5) \int_{-\infty}^{\infty} \delta(\tau+5) d\tau - x(5) \int_{-\infty}^{\infty} \delta(\tau-5) d\tau$$

$$y(t) = x(-5) - x(5)$$

$$(b) \quad y(t) = \frac{1}{2} \int_{-\infty}^{\infty} x(\tau) e^{j\pi/2 \tau} \delta(2\tau-3) d\tau$$

$$\delta(2\tau-3) = \frac{1}{2} \delta(\tau-3/2)$$

$$\frac{1}{2} \delta(\tau-3/2) x(\tau) e^{j\pi/2 \tau} = \frac{1}{2} x(3/2) e^{j3\pi/4}$$

$$\therefore y(t) = \frac{1}{4} x(3/2) e^{j3\pi/4} \int_{-\infty}^{\infty} \delta(\tau-3/2) d\tau$$

$$y(t) = \frac{1}{4} x(3/2) e^{j3\pi/4}$$

PROBLEM 2.19

$$(a) \text{ Let } \tau = at, \text{ then } \int_{-\infty}^{\infty} \delta(at) dt = \int_{-\infty}^{\infty} \delta(\tau) \frac{d\tau}{a}$$
$$= \frac{1}{a} \int_{-\infty}^{\infty} \delta(\tau) d\tau \Rightarrow \delta(at) = \frac{1}{a} \delta(t), a > 0$$

$$\text{for } a < 0, at = \tau \Rightarrow -|a|t = \tau$$
$$\Rightarrow dt = \frac{-d\tau}{|a|}$$

$$\therefore \int_{-\infty}^{\infty} \delta(at) dt = \int_{\infty}^{-\infty} \delta(\tau) \frac{-d\tau}{|a|} = \frac{1}{|a|} \int_{-\infty}^{\infty} \delta(\tau) d\tau$$

$$\therefore \delta(at) = \frac{1}{|a|} \delta(t) \text{ for the general case.}$$

$$(b) \int_{-\infty}^t \delta(\tau) d\tau = \begin{cases} 1, & t > 0 \\ 0, & t < 0 \end{cases} = u(t)$$

$$\therefore \int_{-\infty}^t \delta(\tau - t_0) d\tau = \begin{cases} 1, & t > t_0 \\ 0, & t < t_0 \end{cases} = u(t - t_0)$$

(c)

Recall the rules about integrating delta functions: $\delta(t)$ is nonzero only at $t = 0$, so $x(t)\delta(t) = x(0)\delta(t)$, and $\int_{-\infty}^{\infty} \delta(t) dt = 1$, so $\int_{-\infty}^{\infty} x(t)\delta(t) dt = \int_{-\infty}^{\infty} x(0)\delta(t) dt = x(0) \int_{-\infty}^{\infty} \delta(t) dt = x(0)$. We can time-shift the delta function: $\delta(t - t_0)$ is nonzero only at $t = t_0$, so $x(t)\delta(t - t_0) = x(t_0)\delta(t - t_0)$ and $\int_{-\infty}^{\infty} x(t)\delta(t - t_0) dt = x(t_0)$.

$$i) \int_{-\infty}^{\infty} \cos(2t)\delta(t) dt = \cos(2 \cdot 0) \int_{-\infty}^{\infty} \delta(t) dt = 1.$$

ii) $\delta(t - \frac{\pi}{4})$ is a time-shifted version of $\delta(t)$, and is nonzero only at $t = \frac{\pi}{4}$. So:

$$\int_{-\infty}^{\infty} \sin(2t)\delta(t - \frac{\pi}{4}) dt = \int_{-\infty}^{\infty} \sin(2 \cdot \frac{\pi}{4})\delta(t - \frac{\pi}{4}) dt$$
$$= \sin(\frac{\pi}{2}) \int_{-\infty}^{\infty} \delta(t - \frac{\pi}{4}) dt = \sin(\frac{\pi}{2}) = 1$$

$$2.19 \text{ (c) (iii)} \int_{-\infty}^{\infty} \sin(2t) \delta(t - \pi/6) dt$$

$$= \int_{-\infty}^{\infty} \sin\left(2\frac{\pi}{6}\right) \delta(t - \pi/6) dt = \sin\left(\frac{\pi}{3}\right) \int_{-\infty}^{\infty} \delta(t - \pi/6) dt$$

$$= \sin\left(\frac{\pi}{3}\right) = 0.866$$

$$\text{(iv)} \int_{-\infty}^{\infty} \sin\left[t - \frac{\pi}{4}\right] \delta\left(t - \frac{\pi}{2}\right) dt = \int_{-\infty}^{\infty} \sin\left(\frac{\pi}{2} - \frac{\pi}{4}\right) \delta\left(t - \frac{\pi}{2}\right) dt$$

$$= \sin\left(\frac{\pi}{4}\right) \int_{-\infty}^{\infty} \delta\left(t - \frac{\pi}{2}\right) dt = 0.707$$

$$\text{(v)} \int_{-\infty}^{\infty} \sin\left(t - \frac{\pi}{6}\right) \delta\left(2t - \frac{2\pi}{3}\right) dt = \int_{-\infty}^{\infty} \sin\left(t - \frac{\pi}{6}\right) \delta\left[2\left(t - \frac{\pi}{3}\right)\right] dt$$

$$= \int_{-\infty}^{\infty} \sin\left(\frac{\pi}{3} - \frac{\pi}{6}\right) \delta\left[2\left(t - \frac{\pi}{3}\right)\right] dt = \frac{1}{2} \sin\left(\frac{\pi}{6}\right) = 0.25$$
